

fMRI 101, Part 3

Geoffrey K Aguirre, MD, PhD

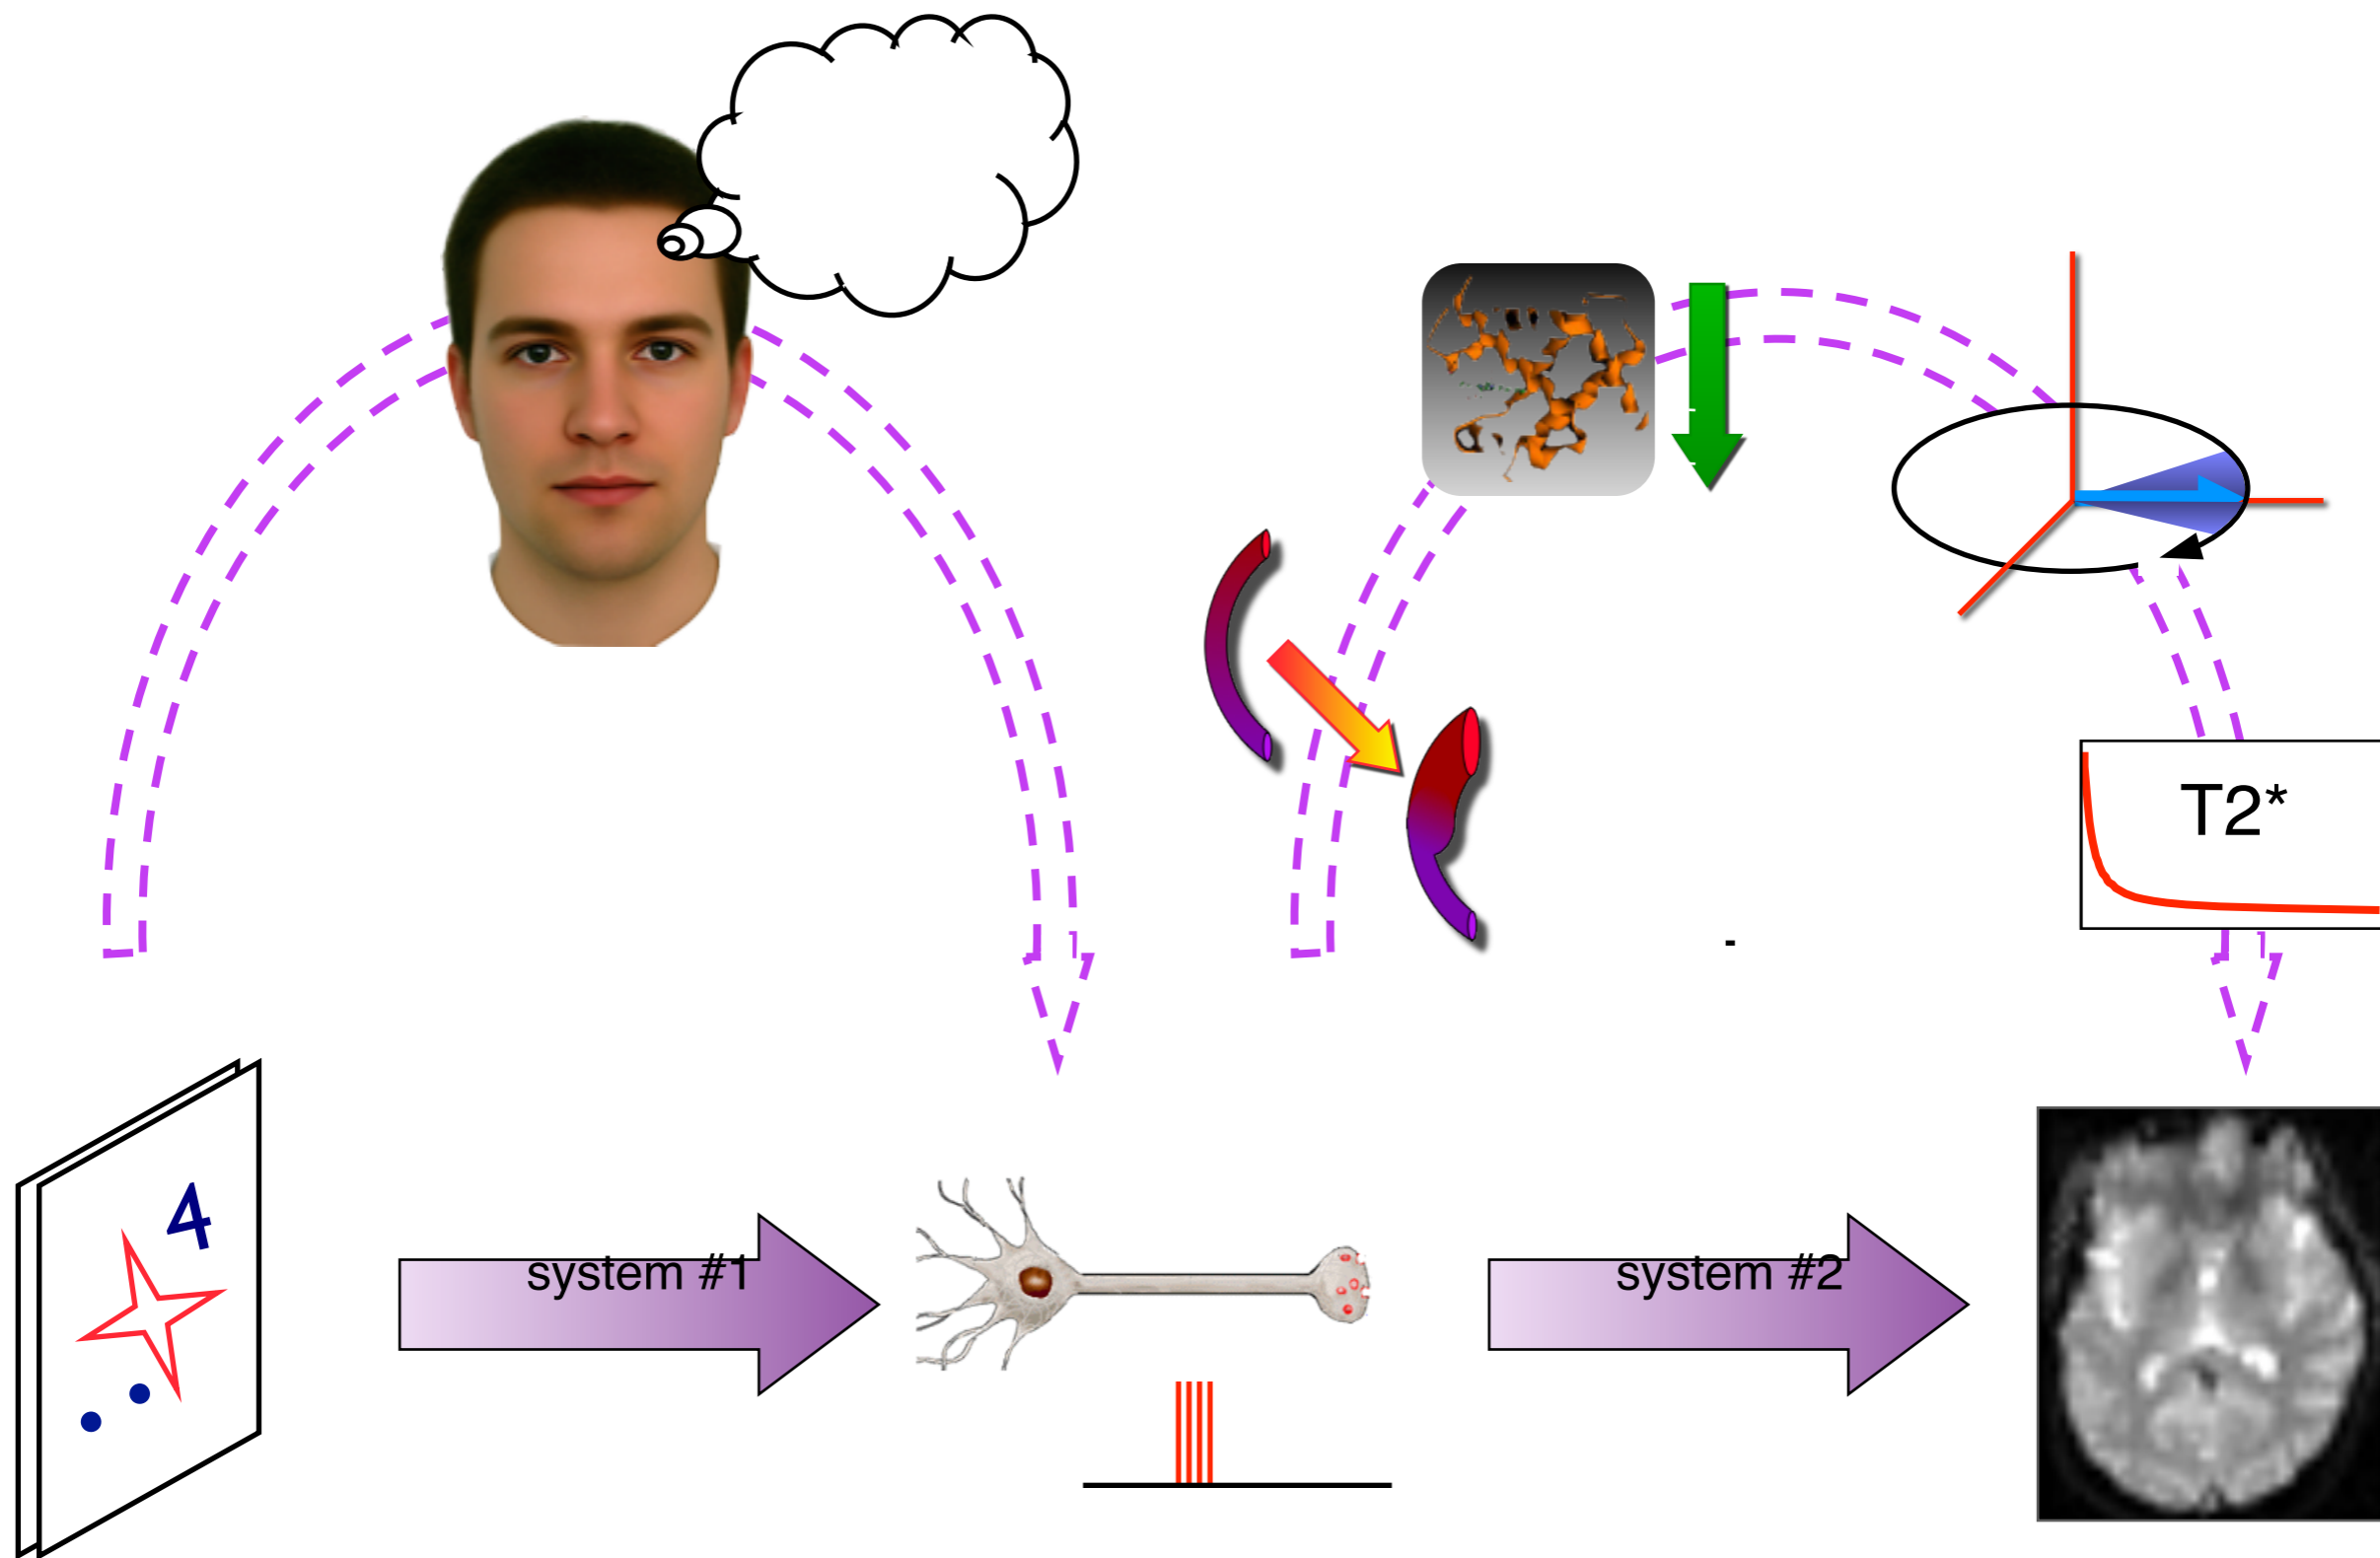

CENTER FOR
COGNITIVE
NEUROSCIENCE

cognition / consciousness

physics / physiology

Two basic types of neuroimaging studies
(and a third that combines the two)

The key question to ask for each

The brain area for “Love”?

Forward inference

which brain areas correspond to
an isolated behavior?

TIME

- Why we love
- What your brain looks like on faith
- What makes us moral
- When worry hijacks the brain
- How w
- Marke

**A menopausal hot flash
increases activity within the
insula**

New

- Inside the grieving brain
- It feels good and everybody does it [scratching]
- Mind reading is now possible
- This is your brain on optimism
- Hot flashes [fMRI of menopause]

The brain area for “Love”?

Forward inference

isolate behavior by subtracting
conditions

The brain area for “Love”?

Spouse vs. Friend over time

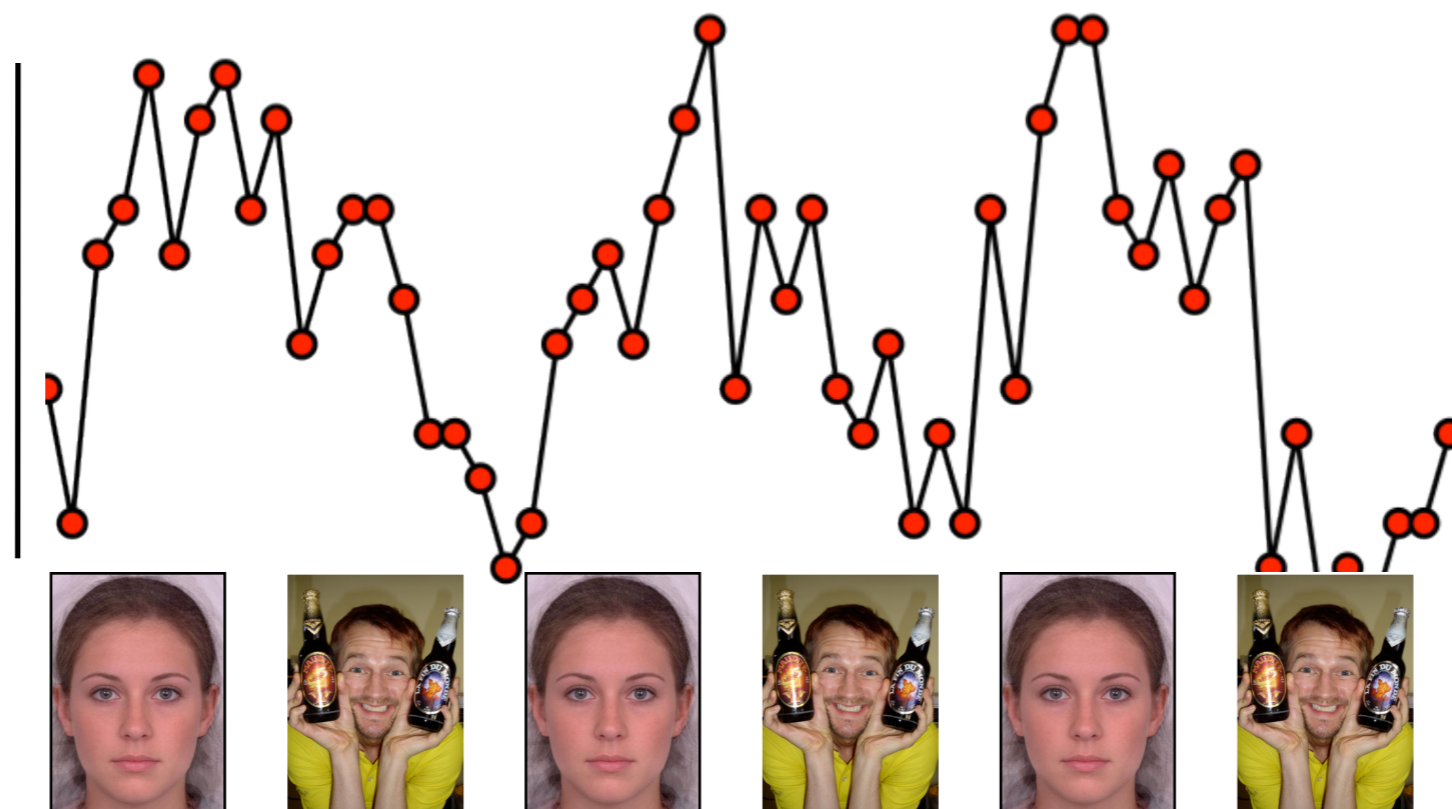

The brain area for “Love”?

Spouse vs. Friend over time

BOLD fMRI signal

The brain area for “Love”?

Forward inference

what if the “subtraction”
includes other mental states?

The brain area for
“working memory”?

Manipulating mental operations

Task versus cognitive process

task

cognitive
process

delayed vs. immediate
match to sample

matching rotated vs. non-
rotated figures

pictures of spouse vs.
pictures of friends

working memory

mental rotation

romantic love

Imaging versus lesion inference

This brain area is necessary for the perception of love

Imaging versus lesion inference

This brain area is necessary for the perception of love

Imaging and lesion inferences are largely independent

The brain area for “Love”?

Forward inference

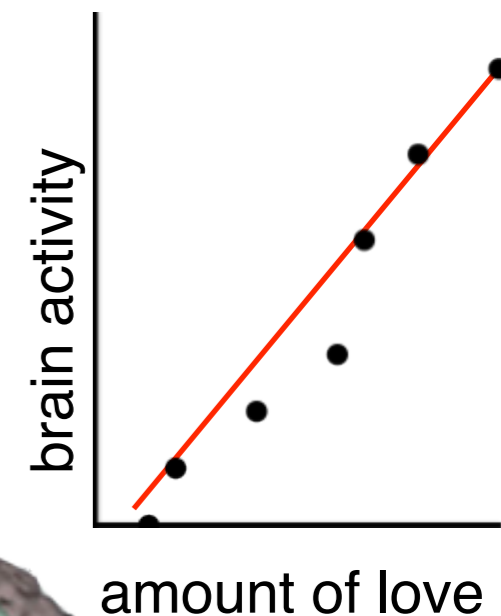

relate variations in the behavior
to variations in neural response

The brain area for “Love”?

Forward inference

relate individual differences in behavior to brain differences

Forward inference

how was the behavior isolated?

Does hearing a bad joke
induce physical pain?

Focal reverse inference

use local brain activity to identify mental
states or emotions a situation evokes

TIME

- Why we love
- What your brain looks like on faith
- What makes us moral
- When worry hijacks the brain
- How w
- Marke

Scratching evokes a sense of pleasure because it decreases memory of pain

New

- Inside the grieving brain
- It feels good and everybody does it [scratching]
- Mind reading is now possible
- This is your brain on optimism
- Hot flashes [fMRI of menopause]

Does hearing a bad joke
induce physical pain?

Focal reverse inference

use local brain activity to identify mental
states or emotions a situation evokes

Does hearing a bad joke
induce physical pain?

Focal reverse inference

what if more than one state can activate
a brain region?

“Boring neuroscience”

Implementation

relate variations in stimulus properties or information processing to response

Focal reverse inference

how strong is the association between local brain activity and the assumed evoked behavior?

Are you lying?

Goal: brain pattern detects lies

LIAR

TIME

- Why we love
- What your brain looks like on faith
- What makes us moral
- When worry hijacks the brain
- How w
- Marke

The scanner can determine if you are lying or telling the truth

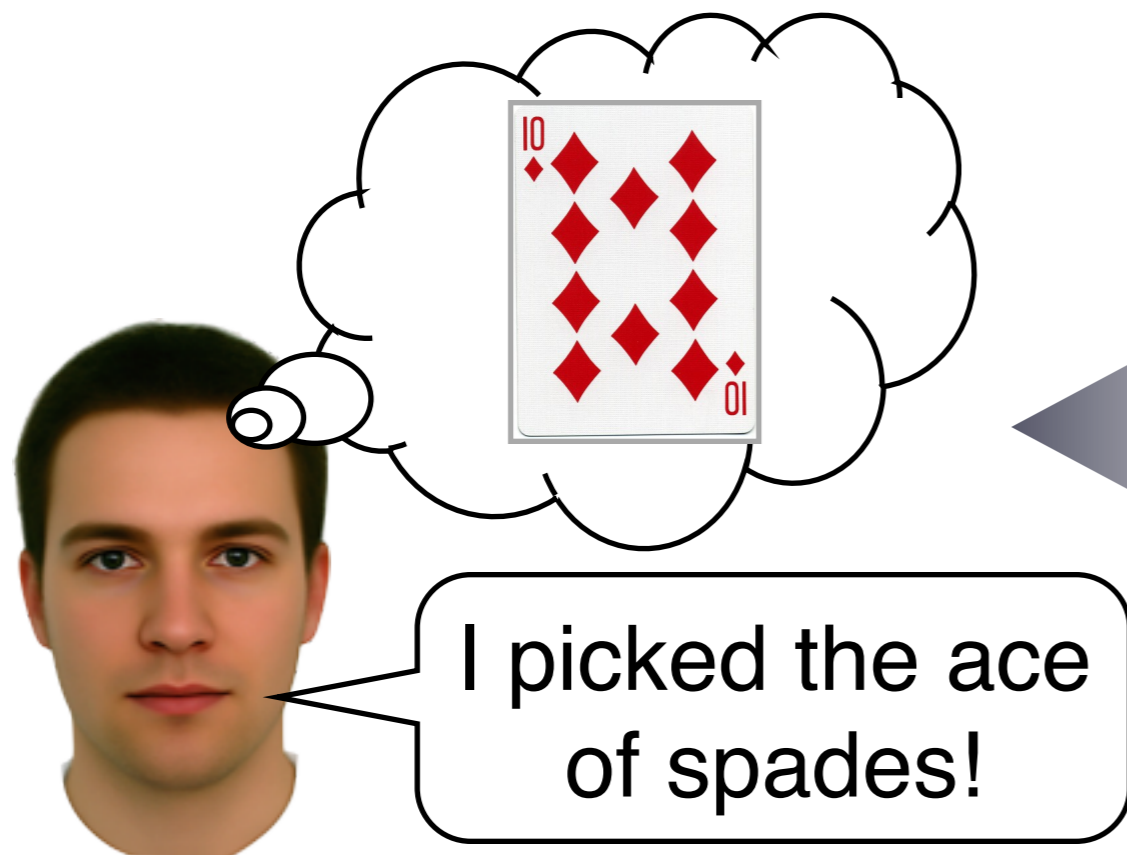

New

- Inside the grieving brain
- It feels good and everybody does it [scratching]
- Mind reading is now possible
- This is your brain on optimism
- Hot flashes [fMRI of menopause]

Are you lying?

Goal: brain pattern detects lies

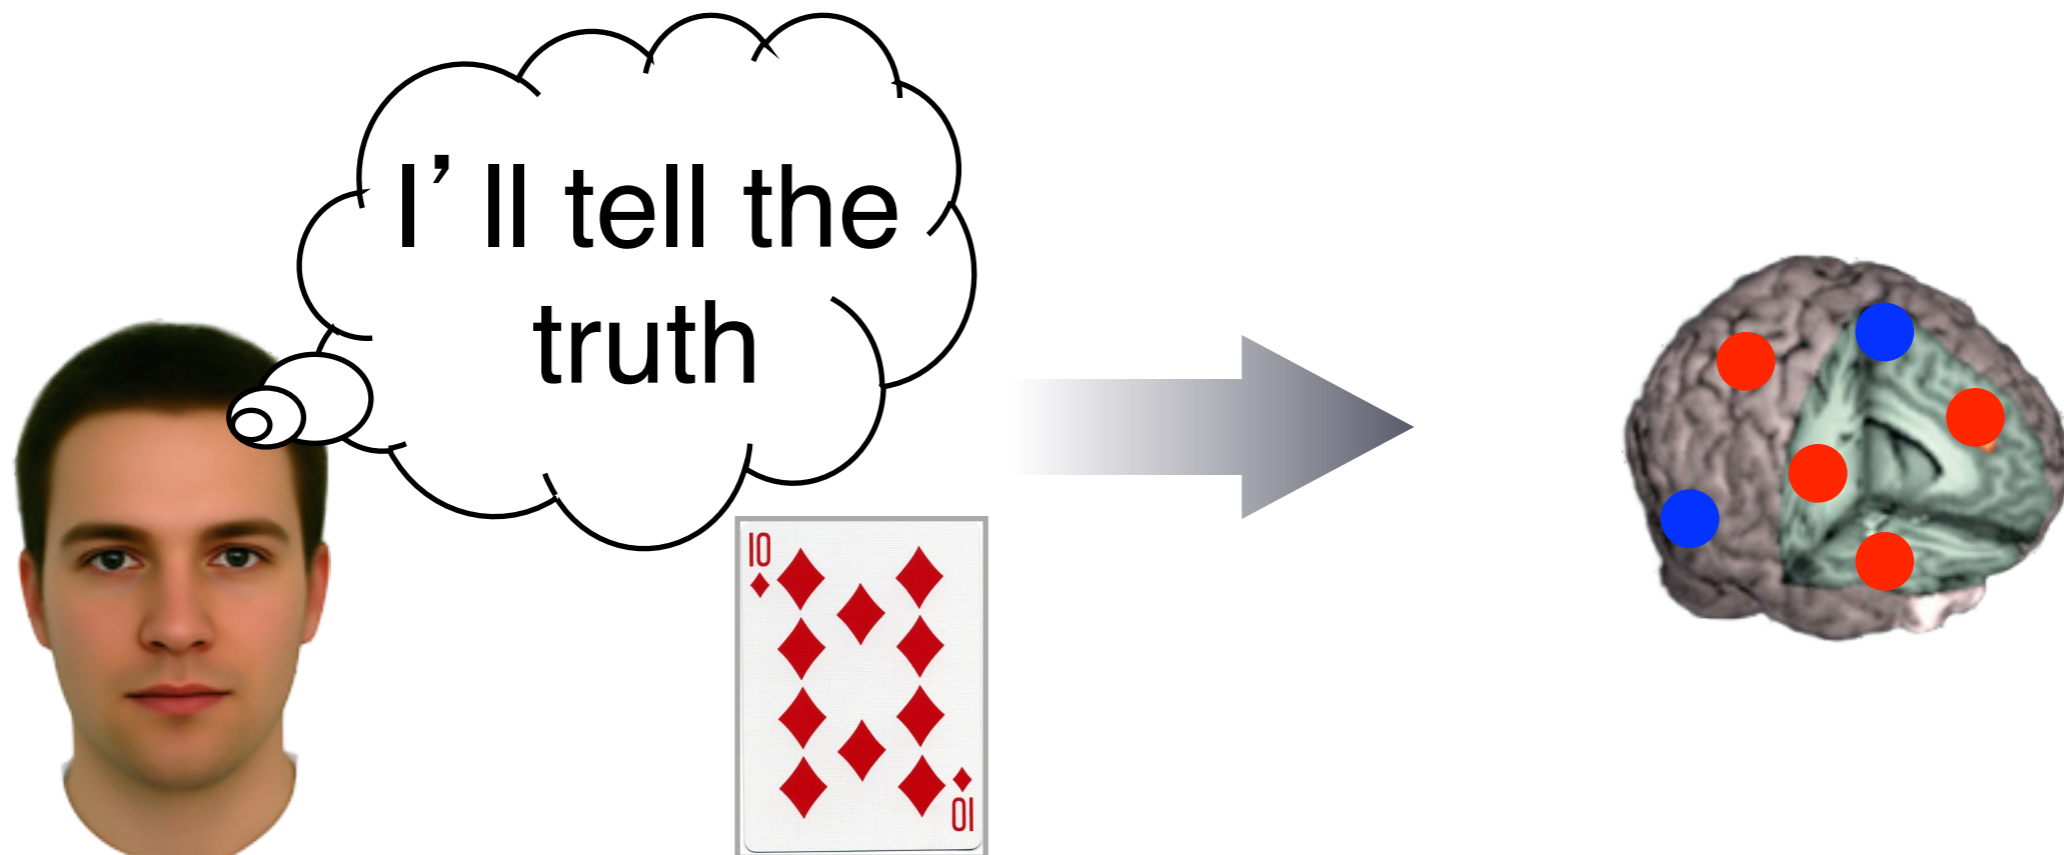

LIAR

Are you lying?

Step 1: forward inference

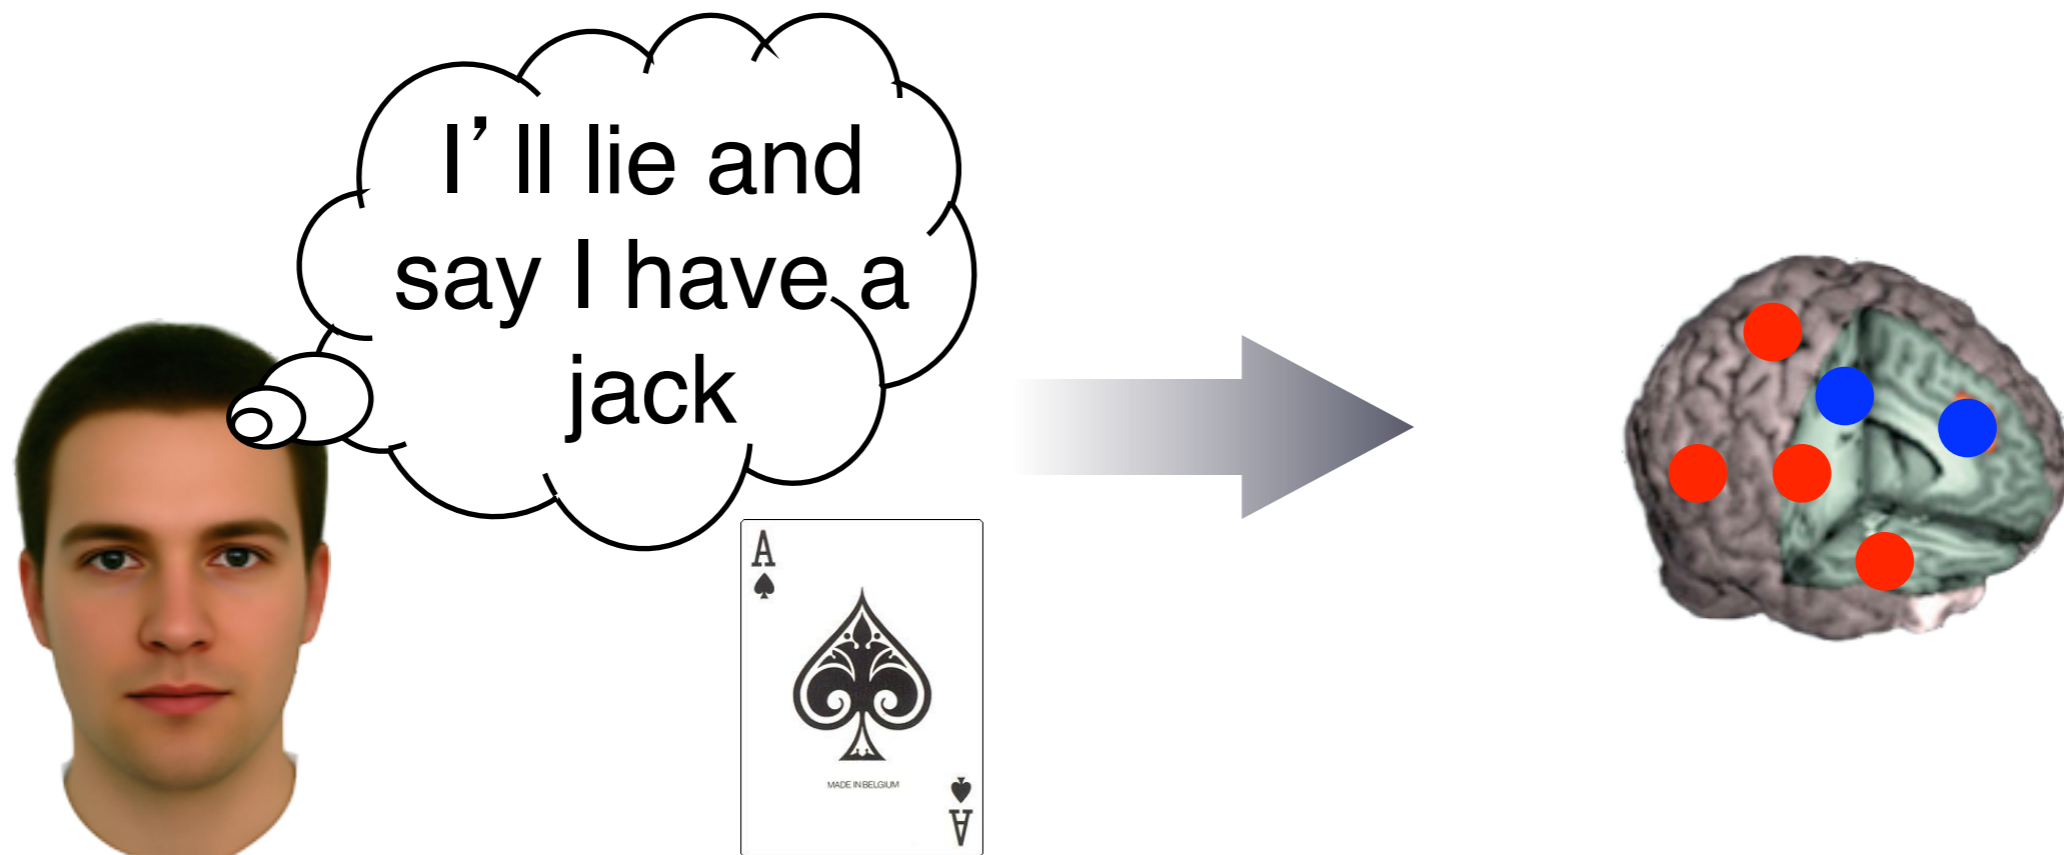

train a computer to learn the pattern of activity evoked by telling truth

Are you lying?

Step 1: forward inference

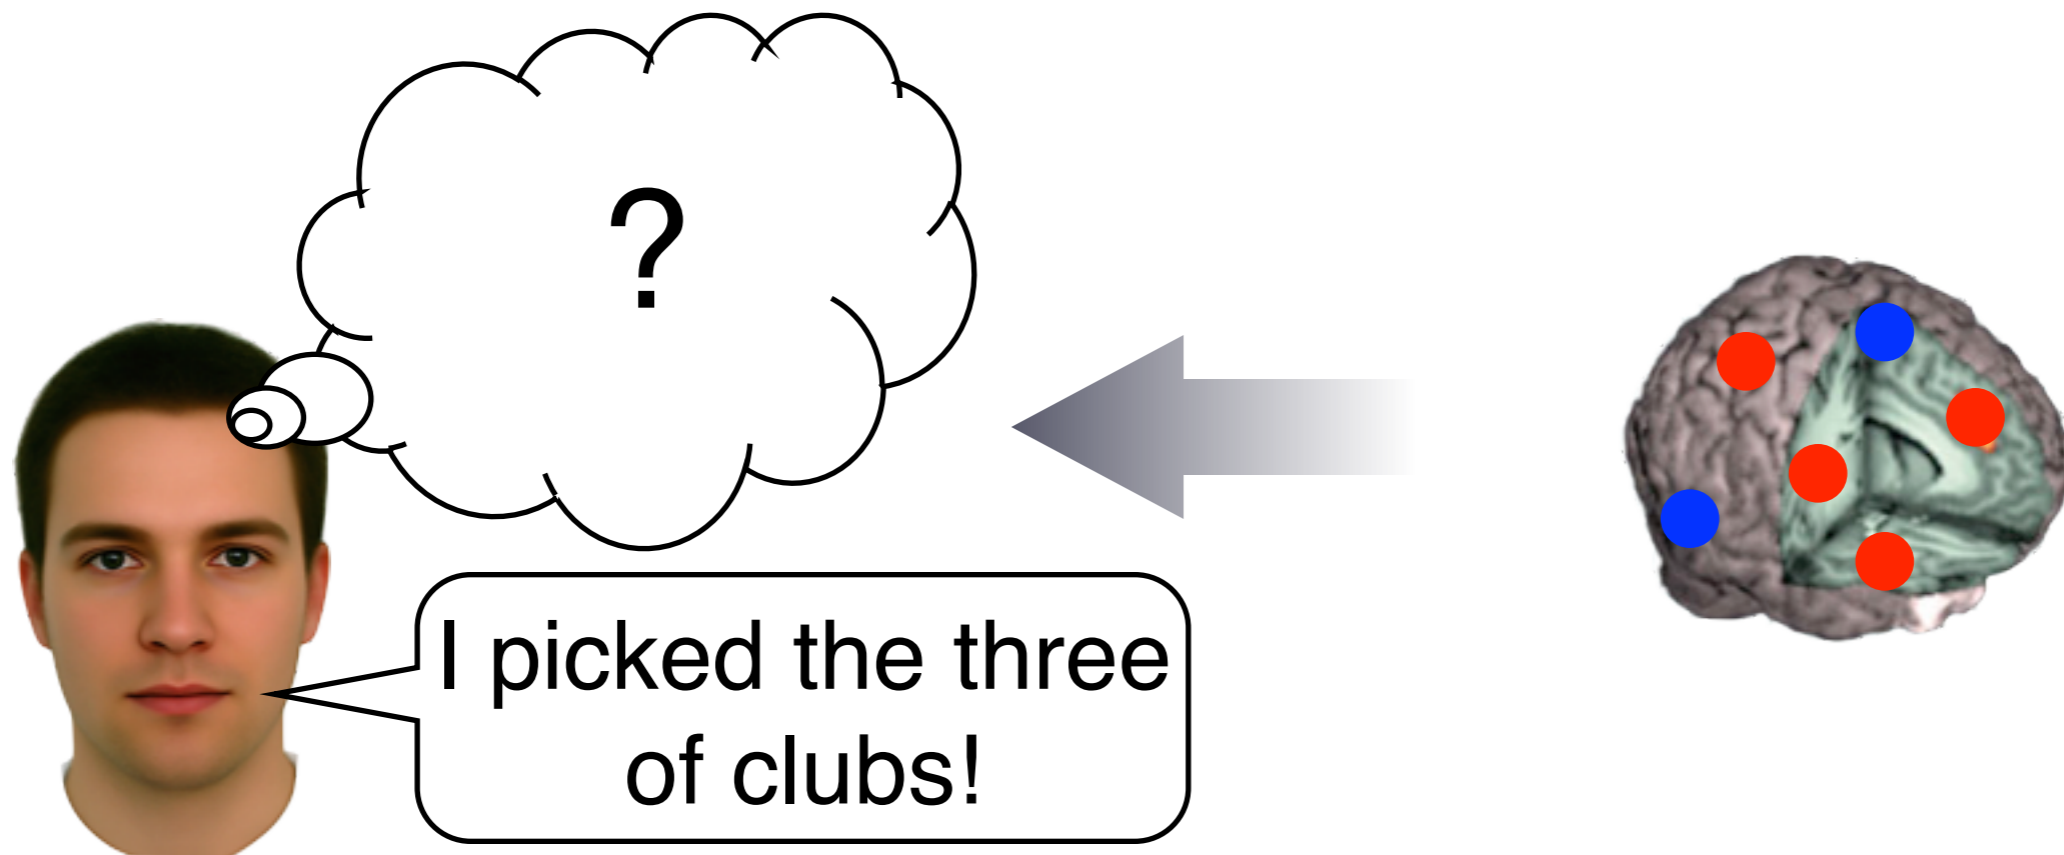

train a computer to learn the pattern of activity evoked by telling lies

Are you lying?

Step 2: reverse inference

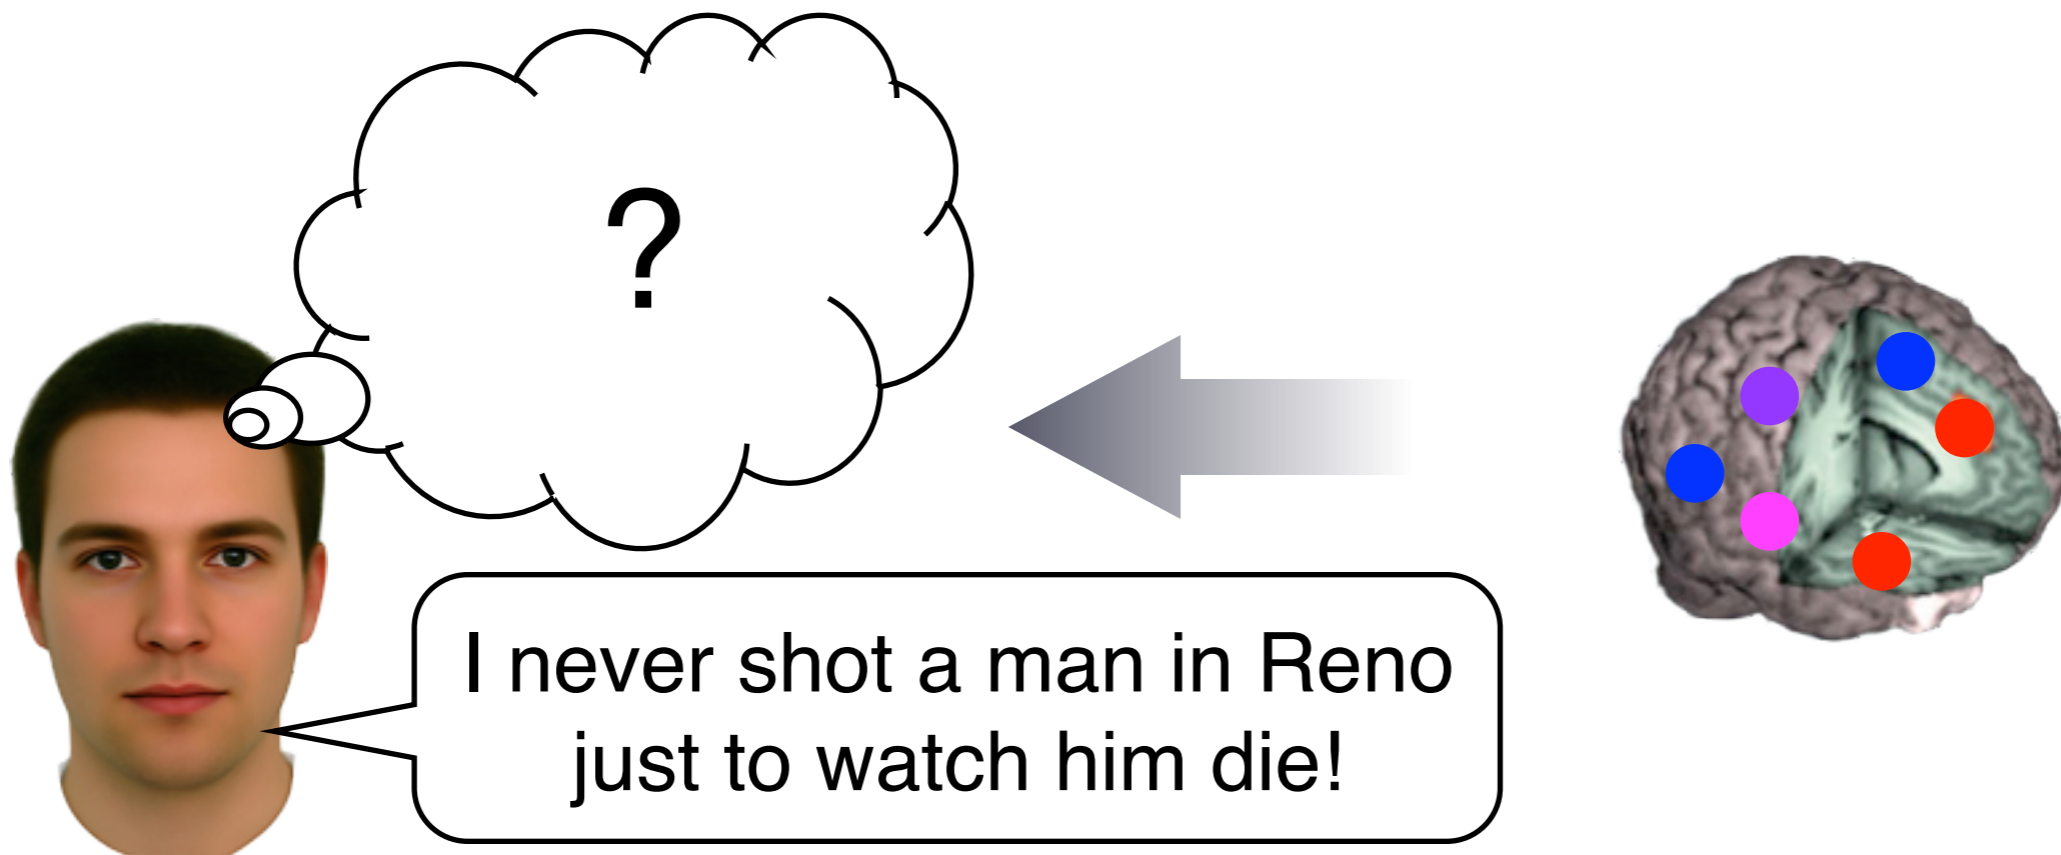

Measure brain activity to discover if a new statement is a truth or lie

Are you lying?

The limitation

Can the classification generalize beyond the training set?

Multi-voxel classification

can the classification be generalized beyond the training context?

Forward inference

determine which brain region is associated with an isolated behavior

Focal reverse inference

use localized brain activity to determine which mental states are evoked by a complex behavior

Multi-voxel classification

use distributed patterns of brain activity to predict which mental state is being experienced

Forward inference

how was the behavior isolated?

Focal reverse inference

how strong is the association between local brain activity and the assumed evoked behavior?

Multi-voxel classification

can the classification be generalized beyond the training context?

Inferences in neuroimaging

State question in terms of neural activity:

- Can my design produce bulk changes in neural activity detectable with fMRI?

Make the inferential framework clear:

- What is the cognitive process and what is the task?
- Am I looking for the neural location of a cognitive process? It's computational implementation? Or am I studying the task itself?

Be cautious of inference across populations:

- Are my subjects impaired at the very cognitive process I seek to study?
- Could the populations differ in hemodynamic instead of neural physiology?
